## 1 Historical Introduction

## 2 Relativistic Quantum Mechanics

### 2.1 Symmetries

If the observations of possible experiments of a system do not change under a transformation, then the transformation is defined to be *symmetry transformation*. Saying in another way, observations under symmetry transformation can be seen as different observers look at the *same* system, and they must find the same probabilities

$$P(\mathcal{R} \rightarrow \mathcal{R}_n) = P(\mathcal{R}' \rightarrow \mathcal{R}'_n) \quad (2.1.1)$$

This is the only condition for a transformation to be a symmetry. Wigner[1] has proved that for any transformation  $\mathcal{R} \rightarrow \mathcal{R}'$  we may define an operator  $U$  on Hilbert space, and the operator is either unitary and linear *or* anti-unitary and anti-linear, such that if  $\Psi \in \mathcal{R}$  then  $U\Psi \in \mathcal{R}'$ .

$$() = \quad (2.1.2)$$
